# Provision (*verb*)

Equip or prepare for a journey.

For data centers, to operationalize equipment.

Incorrectly assumed to be simply installing an operating system on a server.

# Rebar (*noun*)

Structural steel added to concrete foundations to improve their resilience.

For data centers, software that automates infrastructure underlay to build a solid operational foundation.

**Physical Underlay Automation**  
**is**  
**Data Center Plumbing**

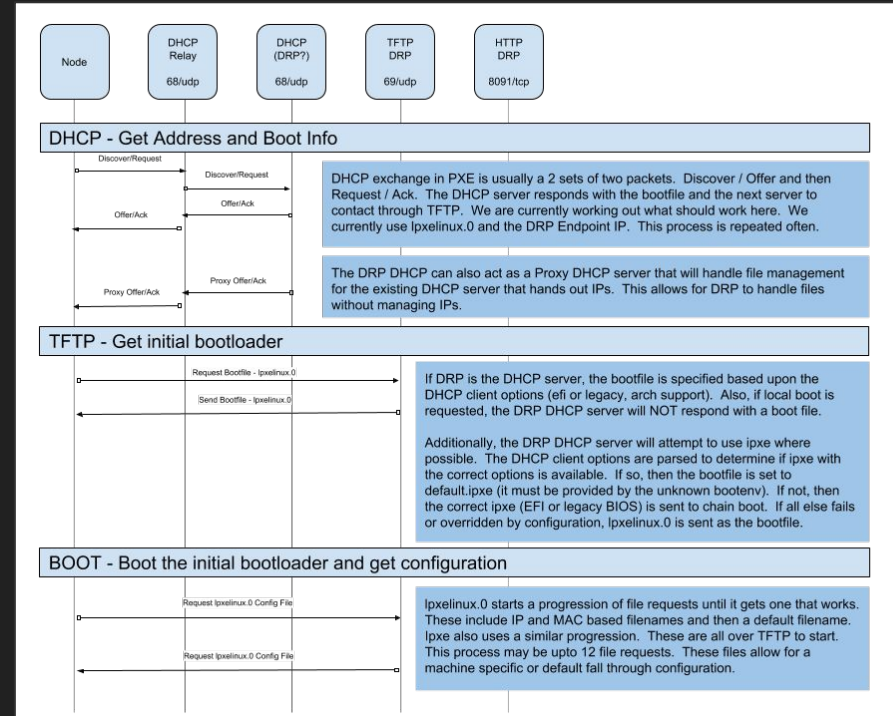

# What is Provisioning?

Much more than installing an operating system using PXE!

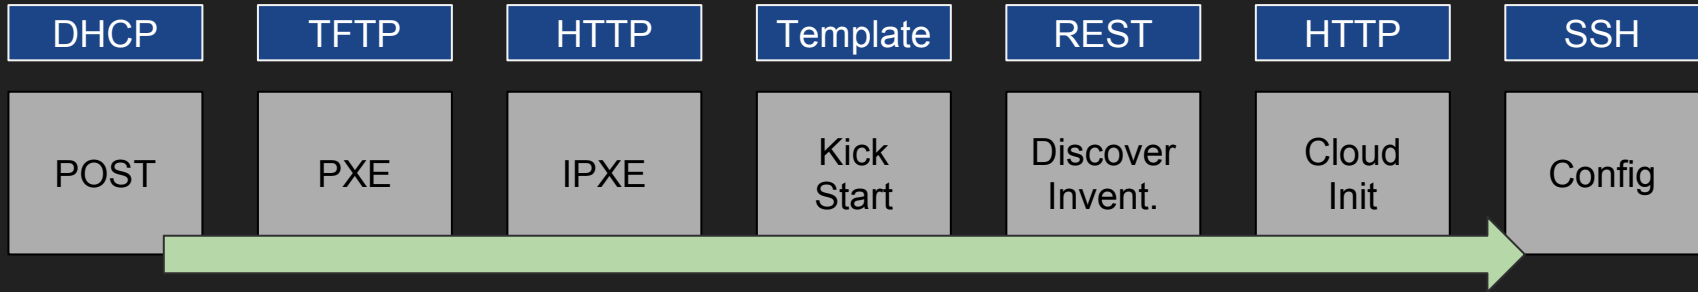

**Provisioning is a multi-step process that interacts with multiple protocols, through multiple boot cycles.**

The process requires both pre and post deployment steps.

Out-of-band (IPMI) management is NOT required for provisionings.

# What makes Provisioning so hard?

Even static provisioning requires integrating many different protocols in a very specific sequence that varies depending on the operating system, hardware and networking configuration.

Digital Rebar “dynamic provisioning” is able to react the the environment on-the-fly to manage the sequence (workflow) based on collected state & external requests.

# Accept that every data center is a snowflake!

If Digital Rebar becomes too opinionated if cannot fully support the existing infrastructure. For example, we have many different DHCP modes including none, primary, forwarding and proxy.

But variation includes network topology, processor architecture, server configuration, operating systems and configuration tooling. Even harder, much of the required information is temporal.

Digital Rebar is a **stateful service** that collects machine and system parameters in a loosely coupled way. Each component and stage defines require and optional data; however, everything is late bound so there is no determinist graph.

Digital Rebar rethinks  
data center automation  
from the *Bare Metal* up
